# ABSTRACT

Dengue infections can result in a wide spectrum of disease severity ranging from an influenza-like illness (dengue fever; DF) to the lifethreatening dengue hemorrhagic fever (DHF)/dengue shock syndrome (DSS). The study was aimed to compare the clinical profile of all patients diagnosed with dengue viral infection at NCMC. This retrospective study included 43 patients infected with dengue virus, age 18 years to 70 years. Laboratory and hematological data were included. Peak of infection occurred in Nov. 2018 and least number of cases were recorded in September 2018. Same observation was seen in previous

year. Common clinical symptoms were fever, headache and myalgia. Common hematological abnormalities were thrombocytopenia and leucopoenia. All patients survived. There was no case of dengue hemorrhagic fever or dengue shock syndrome. Significant differences in the clinical profile is possibly because of infection with different serotypes of dengue virus (DENV), concurrent/sequential infection of more than one serotype, and differences in host immune responses associated with host genetic variations.

**KEYWORDS:** Dengue fever, Leucopoenia, Thrombocytopenia.

# INTRODUCTION

Dengue (Den gay, Dandy) is a mosquito-borne viral illness caused by one of the four serotypes of the dengue virus DENV; (DENV-1 to DENV-4) belonging to the family Flaviviridae. The virus serotypes are closely related but antigenically distinct. Dengue infections can result in a wide spectrum of disease severity ranging from an influenza-like illness (dengue fever; DF) to the life- threatening dengue hemorrhagic fever (DHF)/dengue shock syndrome (DSS). In recent decades, the incidence of dengue infection has increased around the world and has become a major international public health concern. The disease is now endemic in more than 110 tropical and sub-tropical countries. The World Health Organization (WHO) estimates that there may be 50 million dengue infections worldwide every year (1-3). Infection with one serotype of DENV provides lifelong immunity to that serotype but results only in partial and transient protection against subsequent infection by the other three serotypes.

It is possible for a person to be infected as many as four times, once with each serotype. It is well documented Address for correspondence Dr. Mohd Younus Shah

that sequential infection with different DENV serotypes increases the risk of developing DHF. Ninety percent of DHF infections occur in children less than 15 years of age. There is currently no specific treatment for DENV infection, although several potential vaccines are in development; therefore, the only method of preventing DENV transmission is vector (mosquito) control (4-6).

Early clinical features of dengue infection are variable among patients, and initial symptoms are often nonspecific; therefore, specific laboratory tests are necessary for an accurate diagnosis (7-8). According to the US Centers for Disease Control and Prevention (CDC) and the WHO dengue guidelines, the clinical features of DF and DHF are sudden onset of fever, severe headache, myalgias and arthralgias, leucopenia, thrombocytopenia, and hemorrhagic manifestations (8).

It occasionally produces shock and hemorrhage, leading to death. Classic DF symptoms include fever, headache, retro-orbital pain, myalgia and arthralgia nausea, vomiting, and often a rash. Some DF patients develop the more serious form of the disease DHF with symptoms that include a decline in fever and presentation of hemorrhagic manifestations, such as microscopic hematuria, bleeding gums, epistaxis, hematemesis, melena, and ecchymosis. DHF patients develop thrombocytopenia and hemoconcentration; the latter is due to an increase in the concentration of blood cells resulting from the leakage of plasma from the bloodstream (9-10).

These patients may progress into DSS, which can lead to profound shock and death if not treated. Advance clinical symptoms of DSS include severe abdominal pain, protracted vomiting, and a notable change in temperature from fever to hypothermia (2). In this study, we analyzed the variation in clinical features of DENVinfected patients admitted in NCMC Hospital, Panipat.

### **METHODS**

Patients diagnosed with dengue viral infection (n= 43, 19 females and 24 males), aged 18 years to 70 years old, admitted at NCMC from September, 2018 to December, 2018 were included in the study. All the patients were from the neighboring catchment area. All patients were admitted and discharged within a period of 3-7days. All patients received IV fluids and were closely monitored during admission. No patients required platelet transfusion. All patients survived. No

patient went into dengue hemorrhagic fever or dengue shock syndrome.

### Laboratory profile

All patients were tested for NS1 ELISA and were positive.

# Hematological profile

Hematological parameters evaluated were platelet count, prothrombin time (PT), partial thromboplastin time (PTT), hemoglobin (Hb) and hematocrit (HCT) levels, complete blood count (CBC), and white blood cell count (WBC). Blood glucose, urea/creatinine and LFT, X ray chest, ECG were done for all patients as baseline investigations Among the studied patients, none had diabetic and only 3 patients were hypertensive. USG examination showed acalcular cholecystitis in 2, generalized lymphadenopathy in 1 patient.

# **RESULTS**

# Seasonal distribution

The first case of DENV infection detected in September 2018. Total number of cases seen in September were 9, 14 in October, 12 in November and 8 in December. The peak was seen in November as shown in Figure 1 (same as was seen in 2017).

Fig 1: Distribution Of Patients Attending Hospital In 4 Months With Male Female Ratio

Clinical features	Number of patients	%age
Fever	43	100
Rash, flushed	16	37.2
Retro-orbital pain	8	18.6
Headache	11	25,6
Back pain/joint pain	14	32.6
Acalcular cholecystitis	2	4.6
Abdominal pain	3	7.0
Pleural effusion	1	2.3
Bleeding gum	1	2.3
Generalized lymphadenopathy	1	2.3
Dengue triad (fever, headache, rash)	7	16.3
Hemolysis	1	2.3

 Table 1: Clinical And Laboratory Profile Of Dengue Patients Admitted At NCMC

### Hematological profile

Thrombocytopenia (<150,000 platelet count) was observed in all patients. The lowest count was recorded as 5000 and highest was 1.4 lacs. One patient had bleeding gums with platelet count of 5000. This female patient was observed but no platelet transfusion was given and the patient recovered in a couple of days. A young female patient who had delivered 2 months back came with high grade fever and hemolysis. Her Hemoglobin at delivery time was 9.7 g/dL. She dropper her hemoglobin to 3.2 g/dL. She was given 2 units of whole blood and recovered.

### DISCUSSION

### Seasonal distribution

Dengue fever usually commences from mid-June and then there is a surge from September to December. However, in this study cases were seen from September to December and no cases were seen in June, July and August. Probably this is due to increased temperature (global warming).

The pathogenesis of DENV is poorly understood.A complex interaction between immuno-pathologic, viral, and human genetic factors results in a varied DENV disease outcome, which may explain the varied range of clinical presentations observed in this retrospective analysis. A possible reason for the significant differences seen in the clinical expression of the disease may be due to infection with different DENV serotypes and the possibility of concurrent infections with more than one serotype. Co-circulation of multiple DENV serotypes has been reported from many parts of the world, including India during an outbreak of DHF/DSS in 2006. Co- circulation of multiple DENV serotypes would result in an increased risk of concurrent infections (11-12). There is,

however, limited documentation describing concurrent infections with more than one serotype in the same individual (13-14). Furthermore, as already alluded to, sequential infection with more than one serotype is thought to be a major factor for the emergence of DHF (15-16).

Both primary and secondary infection by any of the four DENV serotypes can cause DF and DHF; however, virus virulence is not the only factor to explain differences in host susceptibility to the disease and disease severity. Host immune response variations have been associated with polymorphism in the human genome, which may help explain why some patients develop end-stage complications in dengue disease and others only experience a mild form of the disease (17).

In another study of children with DENV infection, host genetic differences were shown to affect the immune response and consequently, influence disease outcome (18). Dengue infection can have potentially fatal consequences, and to date, vector control methods to prevent the spread of the virus have been unsuccessful (19). Although there are promising vaccine candidates in development, further studies are required for a greater understanding of the humoral immune responses to DENV infection and disease pathogenesis (20-21).

### CONCLUSION

It was observed that significant differences in the clinical presentation of DENV infection. Dengue viral infection is a complicated disease and many factors may be attributed to the differences seen, such as infection with different serotypes or infection with more than one serotype, either sequentially or concurrently. Differences in host genetics and immune responses may also play a role in the severity of infection. The difference in clinical profile of Dengue Fever in our study from the study which we did for the last two years in NCMC, Panipat, was that dengue fever was mild in nature and less patients came with dengue fever. Only 43 patients were seen in these 4 months. This time a young female patient presented with hemolysis. This was an addition to the clinical profile presentation. Dengue fever during these months was very mild and all patients recovered and no one was transfused platelets.
